Abstract

068

Most of existing image denoising methods use some statistical models such as additive white Gaussian noise (AWGN) to model the noise, and learn image priors from either external data or the noisy image itself to remove noise. However, the noise in real-world noisy images is much more complex than AWGN, and it is hard to be modeled by simple analytical distributions. Therefore, many state-of-the-art denoising methods in literature become much less effective when applied to real noisy images. In this paper, we develop a robust denoiser for real noisy image denoising without explicit assumption on noise models. Specifically, we first learn external priors from a set of clean natural images, and then use the learned external priors to guide the learning of internal latent priors from the given noisy image. The proposed method is simple yet highly effective. Experiments on real noisy images demonstrate that it achieves much better denoising performance than state-of-the-art denoising methods, including those designed for real noisy images.

069

1. Introduction

070

Image denoising is a crucial and indispensable step to improve image quality in digital imaging systems. In particular, with the decrease of size of CMOS/CCD sensors, noise is more easily to be corrupted and hence denoising is becoming increasingly important for high resolution imaging. In literature of image denoising, the observed noisy image is usually modeled as $\mathbf{y} = \mathbf{x} + \mathbf{n}$, where \mathbf{x} is the latent clean image and \mathbf{n} is the corrupted noise. Numerous image denoising methods [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13] have been proposed in the past decades, including sparse representation and dictionary learning based methods [1, 2, 3], nonlocal self-similarity based methods [4, 5, 6, 3, 7], low-rank based methods [8], neural network based methods [9], and discriminative learning based methods [10, 11].

071

Most of the existing denoising methods [1, 2, 4, 5, 6, 3, 7, 8, 9, 10, 11, 12, 13] mentioned above assume noise \mathbf{n} to be additive white Gaussian noise (AWGN). Unfortunately, this assumption is too ideal to be true for real-world noisy im-

ages, where the noise is much more complex than AWGN [14, 15] and varies by different cameras and camera settings (ISO, shutter speed, and aperture, etc.). According to [15], the noise corrupted in the imaging process [is signal dependent and comes from five main sources: photon shot, fixed pattern, dark current, readout, and quantization noise. As a result, many advanced denoising methods in literature becomes much less effective when applied to real-world noisy images. Fig. 1 shows an example, where we apply some representative and state-of-the-art denoising methods, including CBM3D [6], WNNM [8], MLP [9], CSF [10], and TRD [11], to a real noisy image (captured by a Nikon D800 camera with ISO is 3200) provided in [14]. One can see that these methods either remain the noise or over-smooth the image details on this real noisy image.

072

There have been a few methods [16, 17, 18, 14, 19, 20, 21] developed for real noisy image denoising. Almost all of these methods follow a two-stage framework: first estimate the parameters of the assumed noise model (usually Gaussian or mixture of Gaussians (MoG)), and then perform denoising with the estimated noise model. Again, the noise in real noisy images is very complex and hard to be modeled by explicit distributions such as Gaussian and MoG. Fig. 1 also shows the denoised results of two state-of-the-art real noisy image denoising methods, Noise Clinic [19, 20] and Neat Image [21]. One can see that these two methods do not perform well on this noisy image either.

073

This work aims to develop a robust solution for real noisy image denoising without explicitly assuming certain noise models. To achieve this goal, we propose to first learn image priors from external clean images, and then employ the learned external priors to guide the learning of internal latent priors from the given noisy image. The flowchart of the proposed method is illustrated in Fig. 3. We first extract millions of patch groups from a set of high quality natural images, with which a Gaussian Mixture Model (GMM) is learned as the external prior. The learned GMM prior model is used to cluster the patch groups extracted from the given noisy image, and then a hybrid orthogonal dictionary (HOD) is learned as the internal prior for image denoising. Our proposed denoising method is simple and ef-

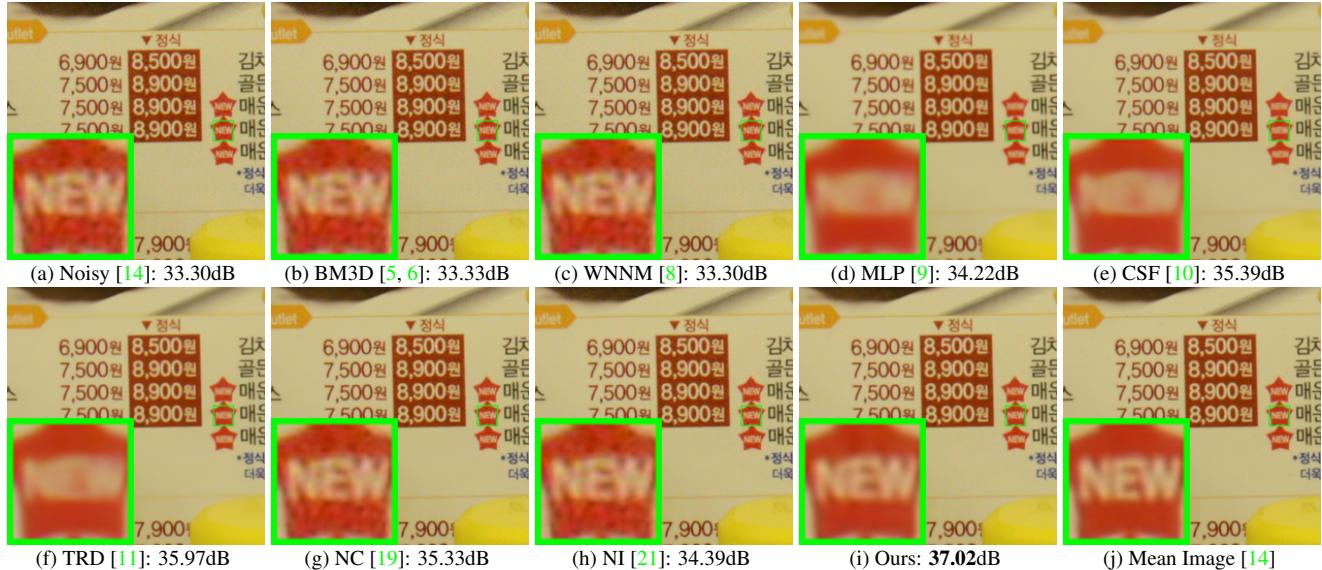

Figure 1. Denoised images of the real noisy image “Nikon D800 ISO 3200 A3” from [14] by different methods. The images are better viewed by zooming in on screen.

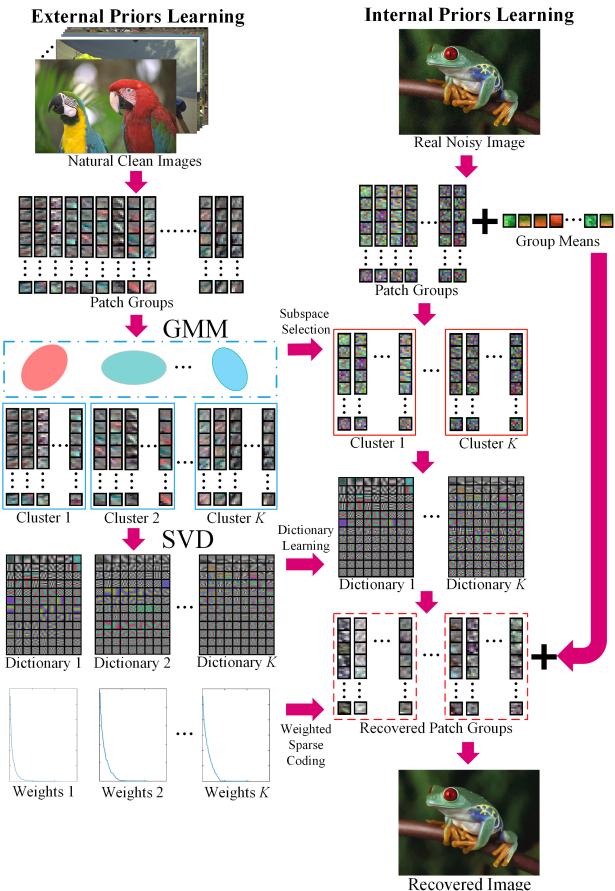

Figure 2. Flowchart of the proposed external prior guided internal prior learning and real noisy image denoising framework.

ficient, yet our extensive experiments on real noisy images clearly demonstrate its better denoising performance than the current state-of-the-arts.

2. Related Work

2.1. Internal vs. External Prior Learning

Image priors are playing a key role in image denoising [7, 13, 1, 22, 3, 23]. There are mainly two categories of prior learning methods. 1) External prior learning methods [12, 7, 13] learn priors (e.g., dictionaries) from a set of external clean images, and the learned priors are used to recover the latent clean image from noisy images. 2) Internal prior learning methods [1, 3, 22, 23] directly learn priors from the given noisy image, and the image denoising is often done simultaneously with the prior learning process. It has been demonstrated [7, 13] that the external priors learned from natural clean images are effective and efficient for image denoising problem, but they are not adaptive to the given noisy image so that some fine-scale image structures may not be well recovered. By contrast, the internal priors are adaptive to content of the given image, but the learning processing are usually slow. In addition, most of the internal prior learning methods [1, 3, 22, 23] assume AWGN noise, making the learned priors less robust for real noisy images. In this paper, we use external priors to guide the internal prior learning. Our method is not only much faster than the traditional internal learning methods, but also very effective to denoise real noisy images.

2.2. Real Noisy Image Denoising

In the last decade, there are many methods [16, 17, 19, 20, 18, 14] for blind image denoising problem. These methods can be applied to real noisy image denoising directly. Liu *et al.* [16] proposed to use “noise level function” to estimate the noise and then use Gaussian conditional random

216 field to obtain the latent clean image. Gong et al. [17] models the noise by mixed ℓ_1 and ℓ_2 norms and remove the
 217 noise by sparsity prior in the wavelet transform domain. Recently, Zhu et al. proposed a Bayesian model [18] which
 218 approximates and removes the noise via low-rank mixture
 219 of Gaussians. The method of “Noise Clinic” [19, 20] and the software of Neat Image [21] are developed specifically
 220 for real noisy image denoising. “Noise Clinic” [19, 20] generalizes the NL-Bayes model [24] to deal with blind noise
 221 and achieves state-of-the-art performance. However, these
 222 methods largely depends on the modeling of noise in real
 223 noisy images which is hard to be modeled by explicit distri-
 224 butions. Besides, the parametric estimation of the Gaussian
 225 or MoG distribution is often time consuming.
 226

231 3. External Prior Guided Internal Prior Learn- 232 ing

233 In this section, we first describe the learning of external
 234 prior, and then describe in detail the guided internal prior
 235 learning. Finally, the denoising algorithm with the learned
 236 priors is presented.

237 3.1. Learn External Patch Group Priors

238 The nonlocal self-similarity based patch group (PG) [7] has proved to be a very effective unit for image prior learning.
 239 In this work, we also extract PGs from natural clean images to learn priors. A PG is a group of similar patches to a local patch.

240 In our method, each local patch is extracted from a
 241 RGB image with patch size $p \times p \times 3$. We search the
 242 M most similar patches to this local patch (including the
 243 local patch itself) in a $W \times W$ local region around it.
 244 Each patch is stretched to a patch vector $\mathbf{x}_m \in \mathbb{R}^{3p^2 \times 1}$
 245 to form the PG $\{\mathbf{x}_m\}_{m=1}^M$. The mean vector of this PG is
 246 $\boldsymbol{\mu} = \frac{1}{M} \sum_{m=1}^M \mathbf{x}_m$, and the group mean subtracted PG is
 247 defined as $\bar{\mathbf{X}} \triangleq \{\bar{\mathbf{x}}_m = \mathbf{x}_m - \boldsymbol{\mu}\}$.

248 Assume we extract a number of N PGs from a set
 249 of external natural images, and the n -th PG is $\bar{\mathbf{Y}}_n \triangleq$
 250 $\{\bar{\mathbf{x}}_{n,m}\}_{m=1}^M, n = 1, \dots, N$. A Gaussian Mixture Model
 251 (GMM) is learned to model the PG prior. The overall log-
 252 likelihood function is

$$253 \ln \mathcal{L} = \sum_{n=1}^N \ln \left(\sum_{k=1}^K \pi_k \prod_{m=1}^M \mathcal{N}(\bar{\mathbf{x}}_{n,m} | \boldsymbol{\mu}_k, \Sigma_k) \right). \quad (1)$$

254 The learning process is similar to the GMM learning in
 255 [7, 13]. Finally, a GMM model with K Gaussian compo-
 256 nents is learned, and the learned parameters include mix-
 257 ture weights $\{\pi_k\}_{k=1}^K$, mean vectors $\{\boldsymbol{\mu}_k\}_{k=1}^K$, and covariance
 258 matrices $\{\Sigma_k\}_{k=1}^K$. Note that the mean vector of each
 259 cluster is naturally zero, i.e., $\boldsymbol{\mu}_k = \mathbf{0}$.

260 To better describe the subspace of each Gaussian com-
 261 ponent, we perform singular value decomposition (SVD)
 262 on the covariance matrix:

$$263 \Sigma_k = \mathbf{U}_k \mathbf{S}_k \mathbf{U}_k^\top. \quad (2)$$

264 The eigenvector matrices $\{\mathbf{U}_k\}_{k=1}^K$ will be employed as the
 265 external orthogonal dictionary to guide the internal dictio-
 266 nary learning in next sub-section. In Fig. 4 (a) and (b), we
 267 illustrate an external clean image and one orthogonal dictio-
 268 nary learned via GMM on PGs of the external clean im-
 269 age. The singular values in \mathbf{S}_k reflect the significance of
 270 the singular vectors in \mathbf{U}_k . They will also be utilized as
 271 prior weights for weighted sparse coding in our denoising
 272 algorithm.

273 3.2. Guided Internal Prior Learning

274 After the external PG prior is learned, we employ it to
 275 guide the internal PG prior learning for a given real noisy
 276 image. The guidance lies in two aspects. One is that the
 277 external prior can guide the subspace assignment of internal
 278 noisy PGs, while the other is that the external prior could
 279 guide the orthogonal dictionary learning of internal noisy
 280 PGs.

281 3.2.1 Internal Subspace Assignment

282 Given a real noisy image, we extract N (overlapped) lo-
 283 cal patches from it. Similar to the external prior learn-
 284 ing stage, for the n -th local patch we search its M most
 285 similar patches around it to form a noisy PG, denoted by
 286 $\mathbf{Y}_n = \{\mathbf{y}_{n,1}, \dots, \mathbf{y}_{n,M}\}$. Then the group mean of \mathbf{Y}_n ,
 287 denoted by $\boldsymbol{\mu}_n$, is subtracted from each patch by $\bar{\mathbf{y}}_{n,m} =$
 288 $\mathbf{y}_{n,m} - \boldsymbol{\mu}_n$, leading to the mean subtracted noisy PG $\bar{\mathbf{Y}}_n \triangleq$
 289 $\{\bar{\mathbf{y}}_{n,m}\}_{m=1}^M$.

290 The external GMM prior models $\{\Sigma_k\}_{k=1}^K$ basically
 291 characterize the subspaces of natural high quality PGs.
 292 Therefore, we project the noisy PG $\bar{\mathbf{Y}}_n$ into the subspaces
 293 of $\{\Sigma_k\}_{k=1}^K$ and assign it to the most suitable subspace
 294 based on the posterior probability:

$$295 P(k|\bar{\mathbf{Y}}_n) = \frac{\prod_{m=1}^M \mathcal{N}(\bar{\mathbf{y}}_{n,m} | \mathbf{0}, \Sigma_k)}{\sum_{l=1}^K \prod_{m=1}^M \mathcal{N}(\bar{\mathbf{y}}_{n,m} | \mathbf{0}, \Sigma_l)} \quad (3)$$

296 for $k = 1, \dots, K$. Then $\bar{\mathbf{Y}}_n$ is assigned to the component
 297 with the maximum A-posteriori (MAP) probability
 298 $\max_k P(k|\bar{\mathbf{Y}}_n)$.

299 3.2.2 Guided Orthogonal Dictionary Learning

300 Assume we have assigned all the internal noisy PGs
 301 $\{\bar{\mathbf{Y}}_n\}_{n=1}^N$ to their corresponding most suitable subspaces in
 302 $\{\mathcal{N}(\mathbf{0}, \Sigma_k)\}_{k=1}^K$. For the k -th subspace, the noisy PGs as-
 303 signed to it are $\{\bar{\mathbf{Y}}_{k,n}\}_{n=1}^{N_k}$ where $\bar{\mathbf{Y}}_{k,n} = [\bar{\mathbf{y}}_{k,n,1}, \dots, \bar{\mathbf{y}}_{k,n,M}]$
 304 and $\sum_{k=1}^K N_k = N$. We propose to learn an orthogonal dictio-
 305 nary \mathbf{D}_k from each set of PGs $\bar{\mathbf{Y}}_{k,n}$ with the guidance of
 306 the corresponding external orthogonal dictionary \mathbf{U}_k (Eqn.
 307 (2)) to characterize the internal PG prior. The reasons that
 308 we learn orthogonal dictionaries are two-fold. Firstly, the
 309 PGs $\bar{\mathbf{Y}}_{k,n}$ are in a subspace of the whole space of all PGs,
 310

324 therefore, there is no necessary to learn a redundant over-
 325 complete dictionary to characterize it, while an orthonormal
 326 dictionary has naturally zero *mutual incoherence* [25].
 327 Secondly, the orthogonality of dictionary can make the en-
 328 coding in the testing stage very efficient, leading to an ef-
 329 ficient denoising algorithm (please refer to sub-section 3.3
 330 for details).

331 We let the orthogonal dictionary \mathbf{D}_k be $\mathbf{D}_k \triangleq$
 332 $[\mathbf{D}_{k,E} \mathbf{D}_{k,I}] \in \mathbb{R}^{3p^2 \times 3p^2}$, where $\mathbf{D}_{k,E} = \mathbf{U}_k(:, 1 : 3p^2 -$
 333 $r) \in \mathbb{R}^{3p^2 \times r}$ is the external sub-dictionary and it includes
 334 the first r most important eigenvectors of \mathbf{U}_k , and the in-
 335 ternal sub-dictionary $\mathbf{D}_{k,I}$ is to be adaptively learned from
 336 the noisy PGs $\{\bar{\mathbf{Y}}_{k_n}\}_{n=1}^{N_k}$. The rationale to design \mathbf{D}_k as a
 337 hybrid dictionary is as follows. The external sub-dictionary
 338 $\mathbf{D}_{k,E}$ is pre-trained from external clean data, and it repre-
 339 sents the k -th latent subspace of natural images, which is
 340 helpful to reconstruct the common latent structures of im-
 341 ages. However, $\mathbf{D}_{k,E}$ is general to all images and it is not
 342 adaptive to the given noisy image. Some fine-scale details
 343 specific to the given image may not be well characterized by
 344 $\mathbf{D}_{k,E}$. Therefore, we learn an internal sub-dictionary $\mathbf{D}_{k,I}$ to
 345 supplement $\mathbf{D}_{k,E}$. In other words, $\mathbf{D}_{k,I}$ is to reveal the
 346 latent subspace adaptive to the input noisy image, which
 347 cannot be effectively represented by $\mathbf{D}_{k,E}$.

348 For notation simplicity, in the following development we
 349 ignore the subspace index k for $\bar{\mathbf{Y}}_{k_n}$ and \mathbf{D}_k , etc. The
 350 learning of hybrid orthogonal dictionary \mathbf{D} is performed un-
 351 der the following weighted sparse coding framework:

$$\begin{aligned} & \min_{\mathbf{D}_i, \{\alpha_{n,m}\}} \sum_{n=1}^N \sum_{m=1}^M (\|\bar{\mathbf{y}}_{n,m} - \mathbf{D}\alpha_{n,m}\|_2^2 + \sum_{j=1}^{3p^2} \lambda_j |\alpha_{n,m,j}|) \\ & \text{s.t. } \mathbf{D} = [\mathbf{D}_e \mathbf{D}_i], \mathbf{D}_i^\top \mathbf{D}_i = \mathbf{I}_r, \mathbf{D}_e^\top \mathbf{D}_i = \mathbf{0}, \end{aligned} \quad (4)$$

358 where $\alpha_{n,m}$ is the sparse coding vector of the m -th patch
 359 $\bar{\mathbf{y}}_{n,m}$ in the n -th PG $\bar{\mathbf{Y}}_n$ and $\alpha_{n,m,j}$ is the j -th element of
 360 $\alpha_{n,m}$. λ_j is the j -th regularization parameter defined as

$$\lambda_j = \lambda / (\sqrt{S_k(j)} + \varepsilon), \quad (5)$$

363 where $S_k(j)$ is the j -th singular value of diagonal singu-
 364 lar value matrix \mathbf{S}_k (please refer to Eqn. (2)) and ε is a
 365 small positive number to avoid zero denominator. Noted
 366 that $\mathbf{D}_E = \mathbf{U}_k$ if $r = 3p^2$ and $\mathbf{D}_E = \emptyset$ if $r = 0$. The
 367 dictionary $\mathbf{D} = [\mathbf{D}_E \mathbf{D}_I]$ is orthogonal by checking that:

$$\mathbf{D}^\top \mathbf{D} = \begin{bmatrix} \mathbf{D}_E^\top \\ \mathbf{D}_I^\top \end{bmatrix} [\mathbf{D}_E \mathbf{D}_I] = \begin{bmatrix} \mathbf{D}_E^\top \mathbf{D}_E & \mathbf{D}_E^\top \mathbf{D}_I \\ \mathbf{D}_I^\top \mathbf{D}_E & \mathbf{D}_I^\top \mathbf{D}_I \end{bmatrix} = \mathbf{I} \quad (6)$$

370 We employ an alternating iterative approach to solve the
 371 optimization problem (4). Specifically, we initialize the or-
 372 thogonal dictionary as $\mathbf{D}^{(0)} = \mathbf{U}_k$ and for $t = 0, 1, \dots, T -$
 373 1, we alternatively update $\alpha_{n,m}$ and \mathbf{D} as follows:

375 **Updating Sparse Coefficient:** Given the orthogonal dic-
 376 tionary $\mathbf{D}^{(t)}$, we update each sparse coding vector $\alpha_{n,m}$ by
 377 solving

$$\alpha_{n,m}^{(t)} := \arg \min_{\alpha_{n,m}} \|\bar{\mathbf{y}}_{n,m} - \mathbf{D}^{(t)} \alpha_{n,m}\|_2^2 + \sum_{j=1}^{3p^2} \lambda_j |\alpha_{n,m,j}| \quad (7)$$

381 Since dictionary $\mathbf{D}^{(t)}$ is orthogonal, the problems (7) has a
 382 closed-form solution

$$\alpha_{n,m}^{(t)} = \text{sgn}((\mathbf{D}^{(t)})^\top \bar{\mathbf{y}}_{n,m}) \odot \max(|(\mathbf{D}^{(t)})^\top \bar{\mathbf{y}}_{n,m}| - \lambda, 0), \quad (8)$$

385 where $\lambda = [\lambda_1, \lambda_2, \dots, \lambda_{3p^2}]$ is the vector of regulariza-
 386 tion parameter and $\text{sgn}(\bullet)$ is the sign function, \odot means
 387 element-wise multiplication. The detailed derivation of
 388 Eqn. (8) can be found in the supplementary file.

389 **Updating Internal Sub-dictionary:** Given the sparse cod-
 390 ing vectors $\alpha_{n,m}^{(t)}$, we update the internal sub-dictionary by
 391 solving

$$\begin{aligned} \mathbf{D}_I^{(t+1)} &:= \arg \min_{\mathbf{D}_I} \sum_{n=1}^N \sum_{m=1}^M (\|\bar{\mathbf{y}}_{n,m} - \mathbf{D} \alpha_{n,m}^{(t)}\|_2^2) \\ &= \arg \min_{\mathbf{D}_I} \|\mathbf{Y} - \mathbf{D} \mathbf{A}^{(t)}\|_F^2 \end{aligned} \quad (9)$$

$$\text{s.t. } \mathbf{D} = [\mathbf{D}_E \mathbf{D}_I], \mathbf{D}_I^\top \mathbf{D}_I = \mathbf{I}_r, \mathbf{D}_E^\top \mathbf{D}_I = \mathbf{0},$$

400 where $\mathbf{A}^{(t)} = [\alpha_{1,1}^{(t)}, \dots, \alpha_{1,M}^{(t)}, \dots, \alpha_{N,1}^{(t)}, \dots, \alpha_{N,M}^{(t)}]$. The
 401 sparse coefficient matrix can be written as $\mathbf{A}^{(t)} =$
 402 $[(\mathbf{A}_E^{(t)})^\top (\mathbf{A}_I^{(t)})^\top]^\top$ where the external part $\mathbf{A}_E^{(t)} \in$
 403 $\mathbb{R}^{(3p^2-r) \times NM}$ and the internal part $\mathbf{A}_I^{(t)} \in \mathbb{R}^{r \times NM}$ rep-
 404 resent the coding coefficients of \mathbf{Y} over external sub-
 405 dictionary \mathbf{D}_E and internal sub-dictionary \mathbf{D}_I , respectively.
 406 According to the Theorem 4 in [26], the problem (9) has
 407 a closed-form solution $\mathbf{D}_I^{(t+1)} = \mathbf{U}_i \mathbf{V}_i^\top$, where $\mathbf{U}_i \in$
 408 $\mathbb{R}^{3p^2 \times r}$ and $\mathbf{V}_i \in \mathbb{R}^{r \times r}$ are the orthogonal matrices ob-
 409 tained by the following SVD

$$(\mathbf{I} - \mathbf{D}_E \mathbf{D}_E^\top) \mathbf{Y} (\mathbf{A}_i^{(t)})^\top = \mathbf{U}_i \mathbf{S}_i \mathbf{V}_i^\top. \quad (10)$$

411 The orthogonality of internal dictionary $\mathbf{D}_I^{(t+1)}$ can be
 412 checked by $(\mathbf{D}_I^{(t+1)})^\top (\mathbf{D}_I^{(t+1)}) = \mathbf{V}_i \mathbf{U}_i^\top \mathbf{U}_i \mathbf{V}_i^\top = \mathbf{I}_r$.
 413 In Figure 4 (c) and (d), we illustrate a denoised image by
 414 our proposed method and one internal orthogonal dictionary
 415 learned from PGs of the given noisy image.

3.3. The Denoising Algorithm

418 The denoising of the given noisy image can be simulta-
 419 neously done with the guided internal dictionary learning
 420 process. Once we obtain the solutions

422 We evaluate the performance of the proposed framework
 423 on denoising real noisy images. The denoising is simulta-
 424 neously done with the guided internal dictionary learning
 425 process. We ignore the index $k \in \{1, \dots, K\}$ of subspace
 426 for notation simplicity. In the denoising stage, for each sub-
 427 space, the group mean vectors $\{\mu_n\}_{n=1}^N$ of corresponding
 428 mean subtracted noisy PGs $\{\bar{\mathbf{Y}}_n\}_{n=1}^N$ are saved for recon-
 429 struction. Until now, we obtain the solutions of sparse coef-
 430 ficient vectors $\{\hat{\alpha}_{n,m}^{(T-1)}\}$ in Eqn. (8) for $n = 1, \dots, N; m =$

432 **Alg. 1:** External Prior Guided Internal Prior Learning
 433 for Real Noisy Image Denoising

434 **Input:** Noisy image \mathbf{y} , external PG prior GMM model
 435 **Output:** The denoised image $\hat{\mathbf{x}}$.
 436 **Initialization:** $\hat{\mathbf{x}}^{(0)} = \mathbf{y}$;
 437 **for** $Ite = 1 : IteNum$ **do**
 438 1. Extracting internal PGs from $\hat{\mathbf{x}}^{(Ite-1)}$;
 439 **for** each PG \mathbf{Y}_n **do**
 440 2. Calculate group mean vector μ_n and form
 441 mean subtracted PG $\bar{\mathbf{Y}}_n$;
 442 3. Subspace selection via Eqn. (3);
 443 **end for**
 444 **for** the PGs in each Subspace **do**
 445 4. External PG prior Guided Internal Orthogonal
 446 Dictionary Learning by solving (4);
 447 5. Recover each patch in all PGs via Eqn. (11);
 448 **end for**
 449 6. Aggregate the recovered PGs of all subspaces to form
 450 the recovered image $\hat{\mathbf{x}}^{(Ite)}$;
 451 **end for**

452
 453
 454 1, ..., M and the orthogonal dictionary $\mathbf{D}_{(T)} = [\mathbf{D}_e \mathbf{D}_i^{(T)}]$
 455 in Eqn. (9). Then the m -th latent clean patch $\hat{\mathbf{y}}_{n,m}$ in the
 456 n -th PG \mathbf{Y}_n is recovered by
 457

$$\hat{\mathbf{y}}_{n,m} = \mathbf{D}_{(T)} \hat{\alpha}_{n,m} + \mu_n, \quad (11)$$

458 where $n = 1, \dots, N; m = 1, \dots, M$. The latent clean im-
 459 age $\hat{\mathbf{x}}$ is reconstructed by aggregating all the estimated PGs.
 460 Similar to [7], we perform the above denoising procedures
 461 for several iterations for better denoising outputs. The pro-
 462 posed denoising algorithm is summarized in Alg. 1.
 463

4. Experiments

464 In this section, we evaluate the performance of the pro-
 465 posed algorithm on real image denoising. To evaluation the
 466 effectiveness of the proposed framework of external prior
 467 guided internal prior learning, we compare it with the meth-
 468 ods with only external prior or only internal prior (Section
 469 4.3). We also compare the proposed algorithm with other
 470 state-of-the-art denoising methods [5, 6, 9, 8, 10, 11, 14,
 471 19, 20, 21] (Section 4.4).

4.1. The Testing Datasets

472 The comparisons are performed on two standard datasets
 473 in which the images were captured under indoor or out-
 474 door lighting conditions by different types of cameras and
 475 camera settings. The first dataset provided in [20] includes
 476 20 real noisy images collected under uncontrolled outdoor
 477 environment. This dataset does not have “ground truth”
 478 images and hence the objective measurements can not be
 479 performed. In order to evaluate the compared methods on
 480 quantitative measures, we perform experiments on the sec-
 481 ond dataset provided in [14]. It includes 17 real noisy im-
 482 ages and corresponding mean images. The noisy images
 483 were collected under controlled indoor environment. Some
 484 samples can be found in [14]. For each image, the same
 485 scene was shot 500 times under the same camera and cam-
 486 era setting. The mean image of the 500 shots is roughly
 487 taken as the “ground truth”, with which the PSNR can be
 488 computed. Since the 17 images are too large (of size about
 489 $7000 \times 5000 \times 3$) and share repetitive contents, the authors in
 490 [14] performed comparison on 15 cropped images (of size
 491 $512 \times 512 \times 3$). To evaluate the compared methods on more
 492 samples, we cropped the 17 large images from [14] into 60
 493 smaller images (of size $500 \times 500 \times 3$) including different
 494 contents. Some samples are shown in Figure 5. Note that
 495 the noise in our cropped 60 images used in [14] are different
 496 from the noise in the 15 images cropped by the authors of
 497 [14] since they are taken in different shots.

4.2. Implementation Details

500 Our proposed method contains two stages, the external
 501 prior learning stage and the external prior guided internal
 502 learning stage. In the first stage, we set $p = 6$ (so the
 503 patch size is $6 \times 6 \times 3$), $M = 10$ (the number of patches
 504 in a patch group (PG)), $W = 31$ (so the window size for
 505 PG searching is 31×31 , and $K = 32$ (the number of
 506 Gaussians in Gaussian Mixture Model (GMM)). We learn
 507 the external prior via GMM on about 3.6 million PGs ex-
 508 tracted from the Kodak PhotoCD Dataset (<http://r0k.us/graphics/kodak/>), which includes 24 high quality
 509 color images. In the second stage, we set $r = 54$ (the num-
 510 ber of internal atoms in the learned dictionaries), $\lambda = 0.001$
 511 (the sparse regularization parameter), $T = 2$ (the number
 512 of iterations for solving problem (4)), and $IteNum = 4$
 513 (the number of iterations for Alg. 1). All experiments are
 514 performed under the Matlab2014b environment on a ma-
 515 chine with Intel(R) Core(TM) i7-5930K CPU of 3.5GHz
 516 and 32GB RAM.

4.3. Comparison among external, internal and ex- 517 ternal guided internal priors

518 In this section, we compare our proposed method on real
 519 image denoising with external prior based method (denoted
 520 as “External”) and internal prior based method (denoted as
 521 as “Internal”). For the “External” method, we utilize the ex-
 522 ternal dictionaries (i.e., $r = 0$ in Eqn. (5)) for denoising.
 523 For the given noisy image, we extract the PGs and then do
 524 internal subspace selection via Eqn. 3. The denoising is per-
 525 formed via the weighted sparse coding framework proposed
 526 in [7]. For the “Internal” method, the overall framework is
 527 similar to the method of [3]. We employ the GMM model
 528 (also with $K = 32$ Gaussians) to cluster the noisy PGs
 529 extracted from given noisy image into multiple subspaces,
 530 and for each subspace, we utilize the internal orthogonal
 531

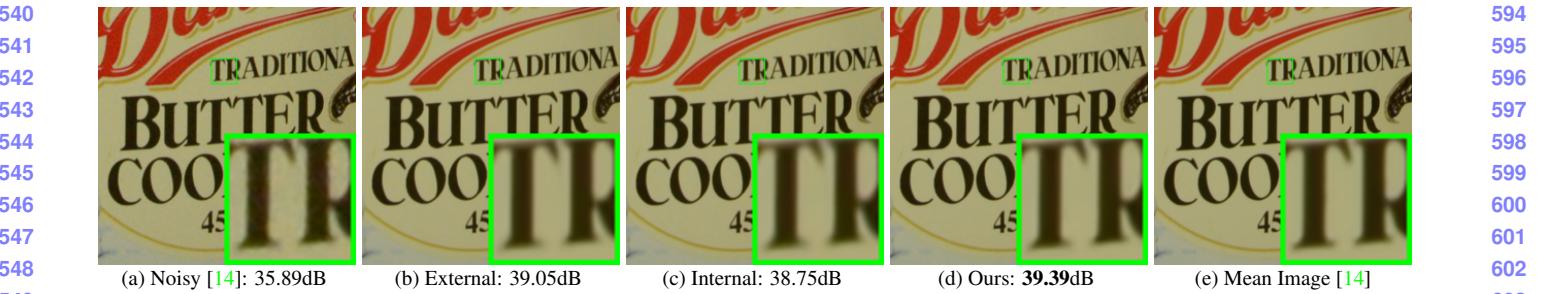

Figure 3. Denoised images of the 96-th cropped image from “Nikon D600 ISO 3200 C1” [14] by different methods. The images are better to be zoomed in on screen.

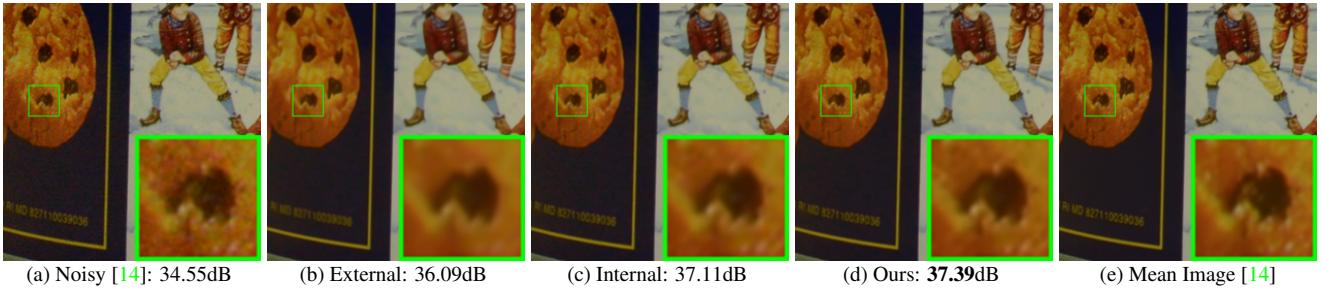

Figure 4. Denoised images of the 94-th cropped image from “Nikon D600 ISO 3200 C1” [14] by different methods. The images are better to be zoomed in on screen.

Figure 5. Some samples cropped from real noisy images of [14].

dictionary obtained via Eqn. (2) by weighted sparse coding framework in [7]. All parameters of the three methods are tuned to achieve best performance.

We compare the above mentioned methods on the 60 cropped images (of size $500 \times 500 \times 3$) from [14]. The average PSNR and speed of these methods are listed in Table 1. It can be seen that our proposed method achieves better PSNR results than the methods of “External” and “Internal”. The speed of our proposed method is much faster than the “Internal” method while only a little slower than the “External” method. We also compare the visual quality of the denoised images by these methods. From the results listed in Figure 3 and Figure 4, we can see that the “External” method is good at recovering structures (Figure 3) while the “Internal” method is good at recovering internal complex textures (Figure 4). And by utilizing both the external and internal priors, our proposed method can recover well both the structures and textures. Noted that the noisy images in Figures 3 and 4 are cropped from the same image captured by Nikon D600 at ISO = 3200 in [14]. Hence, the differences on PSNR and visual quality among these methods only depends on the contents of the cropped images.

Table 1. Average PSNR (dB) results and Run Time (seconds) of the External, the Internal, and our proposed methods on 60 real noisy images (of size $500 \times 500 \times 3$) cropped from [14].

	Noisy	External	Internal	Ours
PSNR	34.51	38.21	38.07	38.75
Time	—	39.57	667.36	41.89

4.4. Comparison with Other Denoising Methods

In this section, we compare the proposed method with other state-of-the-art image denoising methods such as BM3D [5], WNNM [8], MLP [9], CSF [10], TRD [11], Noise Clinic (NC) [19], Cross-Channel (CC) [14], and Neat Image (NI) [21]. The methods of BM3D [5], WNNM [8], MLP [9], CSF [10], and TRD [11] are designed for removing Gaussian noise. For BM3D and WNNM, the level σ of Gaussian noise is very important and is estimated by the method [27]. The other parameters are set as default. For the methods of MLP, CSF, and TRD, we employ their default parameters settings. Since these methods are designed for grayscale images, we utilize them to denoise the R, G, B channels separately for color noisy images. The Noise Clinic (NC) [19] is a blind image denoising method which does not need any noise prior. We also compare with Neat Image (NI), a commercial software for image denoising. Due to its excellent performance, Neat Image (NI) is embedded into Photoshop and Corel PaintShop [21]. The comparisons are performed on the real noisy images from [20] and [14].

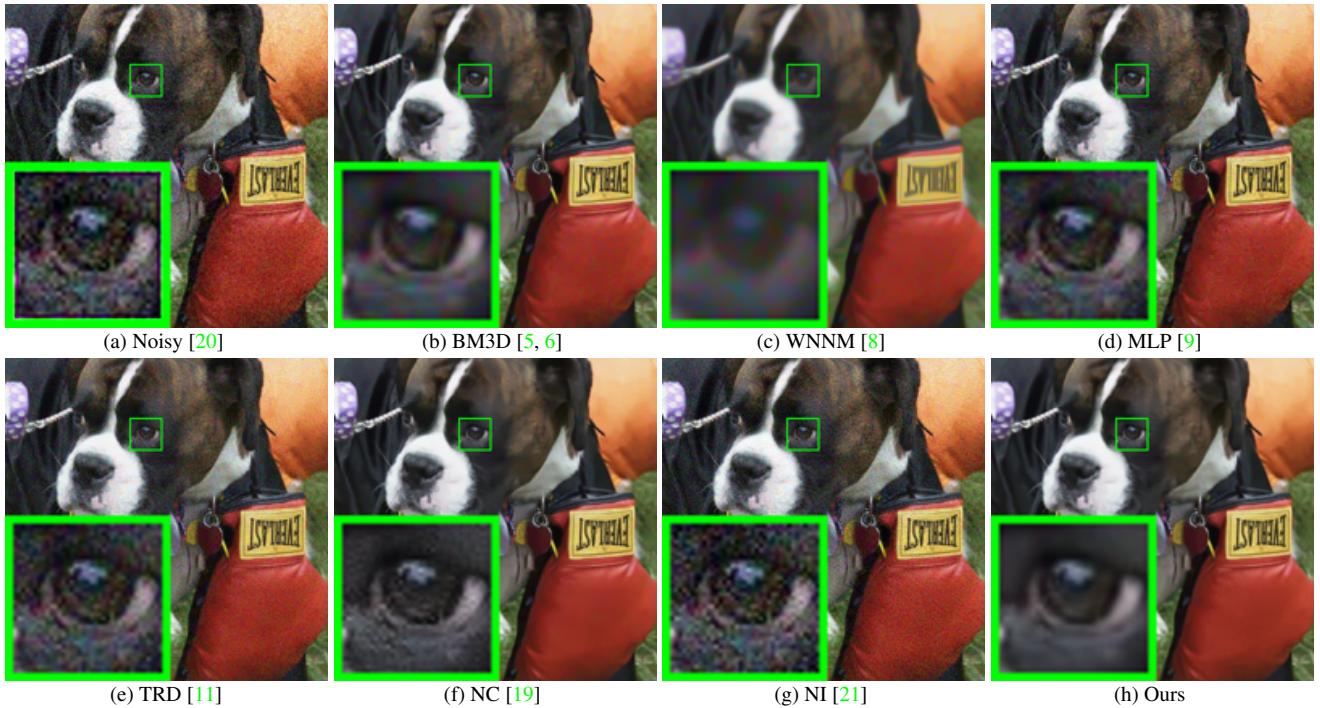

Figure 6. Denoised images of the image “Dog” by different methods. The images are better to be zoomed in on screen.

4.4.1 Comparison on the First Dataset [20]

The real noisy images in the dataset [20] do not have “ground truth” images. On this dataset, we compare the proposed method with the methods of BM3D [5], WNNM [8], MLP [9], TRD [11], Noise Clinic (NC) [19], and Neat Image (NI) [21]. We only compare the visual quality of the denoised images. Figure 6 shows the denoised images of “Dog” by the competing methods. More visual comparisons can be found in the supplementary file. It can be seen that the methods of BM3D, WNNM tend to globally over-smooth the image while locally remain some noise, while the methods of MLP, TRD are likely to remain noise in the whole image. This demonstrates that the methods designed for Gaussian noise are not effective for removing the complex noise in real noisy images. Though Noise Clinic and Neat Image are specifically developed for removing complex noise, they would sometimes fail to recover real noisy images. However, our proposed method recoveries more faithfully the structures and textures (such as the eye area) than the other competing methods.

4.4.2 Comparison on the Second Dataset [14]

The real noisy images in the second dataset [14] have corresponding “ground truth” images. On this dataset, we firstly perform comparison on the 15 cropped images used in [14]. The compared method are BM3D [5], WNNM [8], MLP [9], CSF [10], TRD [11], Noise Clinic (NC) [19], and

Cross-Channel (CC) [14]. The PSNR values are listed in Table 2. As we can see, on most (9 out of the 15) images captured by different cameras and camera settings, our proposed method obtains better PSNR values than the other methods. Noted that, though in [14] a specific model is trained for each camera and camera setting, our proposed general method still gains 0.28dB improvements on PNSR over [14]. We also compare the visual quality of the denoised images by the competing methods. Figure 7 shows the denoised images of a scene captured by Canon 5D Mark 3 at ISO = 3200 by the competing methods. More visual comparisons can be found in the supplementary file. We can see that BM3D, WNNM, NC, NI, and CC would either remain noise or generate artifacts, while MLP, TRD are likely to over-smooth the image. By combining the external and internal priors, our proposed method preserves edges and textures better than other methods.

To evaluate the compared methods on more samples, we then perform denoising experiments on the 60 smaller images cropped from the 17 images provided in [14]. The average PSNR results are listed in Table 3 (the code of [14] is not available so that it is not compared). The numbers in red color and blue color are the best and second best results, respectively. It can be seen that our proposed method achieves much better PSNR results than the other methods. The improvement of our method over the second best method (TRD) is 1dB. Due to the spacial limitations, the visual comparisions are provided in the supplementary file.

Table 2. Average PSNR(dB) results of different methods on 15 cropped real noisy images used in [14].

Camera Settings	Noisy	BM3D	WNNM	MLP	CSF	TRD	NI	NC	CC	Ours

5. Conclusion and Future Work

Image priors are important for solving image denoising problems. The external priors learned from external clean images are generally effective to most images, while the internal priors learned directly from the noisy image are adaptive to the given image but would be biased by the com-

plex noise in real noisy images. In this paper, we demonstrates that, once unifying both the priors in external clean images and internal noisy images, we can achieve much better while still efficient performance on real image denoising problem. Specifically, the external patch group (PG) priors learned on natural clean images can be used to guide the subspace selection and orthogonal dictionary learning of internal noisy PGs from given noisy images. The experiments on real image denoising problem have demonstrated the powerful ability of the proposed method. In the future, we will speed up the proposed algorithm and evaluate the proposed method on other computer vision tasks such as image super-resolution.
